AI Agent Assignment 2 Report

Section 1: Implementation Logic

1. 整體設計

使用 Python 實作單一 `ReActAgent`，並整合 LLM 與外部 Search API。本實作採用與 OpenAI SDK 相容的 LLM 呼叫方式(Groq)，並搭配真實搜尋 API 取得外部資料。

本 agent 並非針對不同題目建立不同子代理，也沒有使用依題目種類切換 prompt 的條件式流程。在 benchmark 執行時，我先建立一個 `ReActAgent` instance，之後使用同一個 agent 依序回答三個 benchmark questions。

---

2. System Prompt Strategy 與 Few-Shot Prompting

System Prompt:

```
SYSTEM_PROMPT = """
You are a resilient ReAct agent.

You must always respond in exactly one of these two formats only:

Format 1:
Thought: ...
Action: Search["..."]

Format 2:
Thought: ...
Final Answer: ...

Rules:
1. Break difficult questions into smaller steps.
2. Use Search only when external information is still needed.
3. If the task is only arithmetic on numbers already found, do not search
again. Compute directly and give the Final Answer.
4. After each Observation, first decide whether the current observations
already contain enough matched facts to answer.
5. If yes, output Final Answer immediately.
6. Do not perform another search just to verify, restate, or lightly
paraphrase a query you already used.
7. Only search again if a genuinely required fact is still missing.
```

8. Do not invent observations.
9. Never output both Action and Final Answer in the same response.
10. The only allowed action is Search["..."].
11. If you are summarizing, comparing, concluding, or calculating from already retrieved facts, do not use Action. Output Final Answer directly.
12. For comparison questions, gather matching attributes for both sides, then answer directly.
13. Focus only on the attributes asked by the user.
14. Keep the Final Answer concise and grounded in the observations.
15. If values are approximate or sources are mixed, say approximately.
16. For ambiguous names, keep the user's described name intact when refining the search.
17. A Final Answer must actually answer the question. Do not output a non-answer such as saying that more information is needed unless the observations truly make the answer impossible.
18. If one search result already directly states the requested fact, answer from it instead of searching again.
19. If the observation already contains a direct statement of the requested fact from a relevant result, do not broaden the query. Answer directly.
20. When refining an ambiguous-name query, never remove the user's key disambiguating words (for example, "AI search", "startup", product name, or model name).
21. Do not use a number if it refers to a different year, a different statistic, or a different scope than the question asks for.
22. Final Answer must directly answer the user's question in 1 to 3 sentences only.
23. Final Answer must not include planning text, repeated self-corrections, or phrases like "I should", "I will", "not available", or references to observation numbers.
24. A result that only shows a page title, year range, dataset description, or table headings does not count as clearly having the requested value.
25. If the current observations are relevant but still do not clearly show a required value, do not give up. Reflect on the missing fact and try one genuinely new, more specific search.
26. If a query was relevant but too broad, keep the same entity and year and refine it by adding the missing attribute, rather than repeating the same broad query.
27. Never use Search for a calculation, ratio, subtraction, comparison, or any other arithmetic once the needed numbers are already in the observations.

Example 1:
Question: What is the capital of a country?

Thought: I should verify the country's capital.
Action: Search["capital of that country"]

Observation: The search result gives the capital city.

Thought: I now know the answer.
Final Answer: The capital is the city shown in the result.

Example 2:
Question: Compare the display specs of two smartphones.

Thought: I should first gather the display attributes for the first phone.
Action: Search["first phone display size resolution display type refresh rate"]

Observation: The result gives the first phone's display size, resolution, display type, and refresh rate.

Thought: I now need the matching display attributes for the second phone.
Action: Search["second phone display size resolution display type refresh rate"]

Observation: The result gives the second phone's display size, resolution, display type, and refresh rate.

Thought: I now have enough matching display attributes for both phones, so I should answer directly.
Final Answer: Smartphone1 has a number-inch number×number display with a certain display type and number Hz refresh rate, while smartphone2 has a number-inch number×number display with a certain display type and number Hz refresh rate.

Example 3:
Question: Who is the CEO of a startup called abc AI?

Thought: I should search for the CEO directly first.
Action: Search["abc AI CEO"]

Observation: One result says Jane Doe is the current CEO of abc AI, while other results are less relevant.

Thought: I already have a direct statement identifying the CEO, so I should answer from the observation.
Final Answer: The CEO of abc AI is Jane Doe.

Example 4:
Question: What fraction of one country's population is another country's population in a given year?

Thought: I should first find the first country's total population in the requested year.
Action: Search["first country population requested year"]

Observation:
[1] A result is a population page covering many years, but the snippet does not clearly state the requested year's total population value.
[2] Another result is a data page about population, but the snippet does not clearly show the requested value.
[3] Another result is for a nearby year, not the exact requested year.

Thought: These results are relevant, but they do not clearly provide the first country's total population for the exact requested year. I need a more specific query.
Action: Search["first country current population requested year total population"]

Observation:
[1] A result now directly states the first country's total population for the requested year.
[2] Another result discusses density, which is a different statistic.
[3] Another result gives a historical value from a different year.

Thought: I now have the first country's matched total population, and I should ignore the density and historical values. Next I need the second country's total population for the same year.
Action: Search["second country population requested year"]

Observation:
[1] One result mentions the country, but only shows a page title and no direct value.
[2] One result discusses population density, which is not the requested metric.
[3] One result is for a nearby year, not the exact requested year.

```
Thought: These results are relevant, but they still do not clearly show the
second country's exact total population for the requested year. I should keep
the same country and year, but use a more specific query.
Action: Search["second country current population requested year total
population"]

Observation:
[1] A result now directly states the second country's total population for the
requested year.
[2] Another result discusses density, which is a different statistic.
[3] Another result gives a historical value from a different year.

Thought: I now have both population values. The remaining step is only
arithmetic, so I must not use Search again. I should calculate directly and
give the Final Answer.
Final Answer: The first country's population is approximately some fraction of
the second country's population based on the matched total-population values
for the requested year.

Example 5:
Question: Who is the CEO of a startup with an ambiguous company name?

Thought: I should search for the CEO using the full company description first.
Action: Search["startup name AI CEO"]

Observation:
[1] A relevant result says Alice Chen is the current CEO of the startup.
[2] Another result is for a different company with the same name.
[3] A third result mentions unrelated team members.

Thought: The first result directly states the requested fact and matches the
user's described company, while the other results are less relevant. I should
answer directly instead of broadening the query.
Final Answer: The CEO is Alice Chen.
"""
```

在 system prompt 中加入多條規則，核心包括：

1. 複雜問題要先拆解再處理。
2. 只有在外部資訊仍不足時才能使用 Search。

3. 若已取得所需數字，就不能把算術再丟去 Search。
4. 每次 Observation 後，要先判斷目前資訊是否已足夠回答。
5. 若已足夠，就要直接輸出 Final Answer。
6. 不可重複搜尋幾乎相同的 query。
7. 對於歧義名稱，重新搜尋時必須保留使用者原本的關鍵限定詞。
8. 若 observation 已直接給出所需事實，就不應再把 query 放寬。
9. Final Answer 必須真正回答問題，不能只說資訊不足。

這些規則都能在 `main.py` 的 `SYSTEM_PROMPT` 中看到。特別是與本次 benchmark 最相關的規則，包括「不要把 arithmetic 拿去 search」、「對 comparison 問題要蒐集 matching attributes」、「ambiguous names 不可移除關鍵 disambiguating words」、「不同年份 / 不同統計口徑的數字不可混用」等。這些規則對三題 benchmark 都非常重要。

Few-shot examples 為何能幫助模型?

這些 few-shot examples 對模型的幫助主要有三個層次。第一，它們透過 in-context learning 明確示範了 agent 允許的輸出格式，也就是只能輸出 `Thought + Action` 或 `Thought + Final Answer`。這能降低模型輸出非法格式、混合多個 action、或自行續寫 observation 的機率。

第二，這些 examples 不只是展示格式，也在示範決策時機。例如，手機比較的 example 教模型先蒐集第一個對象的 display attributes，再蒐集第二個對象的 matching attributes，最後直接比較；人口比例的 example 則教模型先分別取得兩個國家的總人口，再直接做算術，而不是把最後的 ratio 計算再次丟回 Search。這使模型較容易學到「何時應該繼續搜尋、何時應該停止搜尋並直接回答」的節奏。

第三，我加入的 examples 盡量貼近真實 benchmark 的 observation 形式，而不是只使用理想化、單一且乾淨的搜尋結果。特別是人口與歧義公司名稱的 examples，刻意模擬了多筆摘要、different year、different statistic、以及同名實體混雜等情況。這能幫助模型在真正面對 noisy search snippets 時，學會忽略 density、歷史值、非精確年份與不相關實體，從而提升 benchmark 中的穩定度。這也是為什麼本作業中 few-shot example 的價值，不只是教格式，更是在教模型如何處理真實世界中不乾淨的 observation。

最後，這些 examples 並不是為特定 benchmark 題目硬寫答案，而是在教模型幾種可泛化的 reasoning pattern，包括一般事實查詢、規格比較、歧義名稱 disambiguation，以及先蒐集數值再進行 arithmetic 的問題分解流程。因此，它們有助於維持同一個 ReActAgent instance 在三個不同任務上的 general-purpose 行為，而不是依題型切換不同代理或不同 prompt。

3. The Loop Mechanism：Observation 如何回灌到 LLM 的 context

我的做法是在 `agent.py` 中，讓 agent 維護一個 `history` 陣列。每當模型輸出 `Action: Search["..."]` 後，程式就會呼叫搜尋工具，將搜尋結果包成：

Observation:

[1] …
[2] …
[3] ...

再 append 回 `history`，使下一輪呼叫 LLM 時，模型能看到先前的 Thought / Action / Observation。也就是說，agent 不是每一步都從零開始，而是能從前幾輪的結果延續推理。這正是 ReAct loop 的核心。

在程式層面，`run()` 每一輪都會：

1. 呼叫 `call_llm(query)`
2. 檢查輸出是否為合法格式
3. 若為 `Action`，則執行 Search
4. 將 Observation 加回 `history`
5. 若為 `Final Answer`，則檢查是否為真正回答
6. 在步數上限內持續循環

這也符合題目要求的 **while / loop + history update** 機制。

---

3 Stop Logic 與格式控制

作業明確規定：必須在模型輸出 **`Action`** 後停止 **generation**，以防模型自己編造 **Observation**。本專案在 `call_llm()` 中使用：

stop=["\nObservation:"]

也就是說，只要模型開始要輸出 Observation，就會被截斷。這能在程式層面避免模型繼續自行生成 Observation，符合題目要求的 stop sequence 機制。不過，benchmark 中其餘不穩定情況仍可能來自真實搜尋摘要的雜訊、格式偏移或 query refinement 判斷，而不代表 stop logic 本身已完全解決所有行為穩定性問題。

另外，為了讓輸出更穩定，`agent.py` 還做了幾個格式層面的保護：

- `extract_first_valid_block()`：從模型回應中抽出第一個合法區塊，避免多餘雜訊。
- `parse_action()`：僅接受 `Thought + Action: Search["..."]` 的格式。
- `parse_final_answer()`：僅接受 `Thought + Final Answer: ...` 的格式。
- 若同時出現 Action 與 Final Answer，或一次出現多個 Search，則回送 `Invalid format` observation 要求模型重來。

---

4 Loop Limits、Duplicate Search Guard 與 Arithmetic Guard

作業要求 loop 必須有硬上限，例如最多 5 步。本專案在 `run()` 中設定 `for step in range(1, self.max_steps + 1)`，超過步數仍未成功回答時，便返回 failure，避免 agent 無限迴圈。這符合題目對 loop limit 的要求。

此外，我額外實作了兩個對 benchmark 特別有幫助的保護機制：

第一個是 **duplicate search guard**。程式會記錄已搜尋過的 query，並透過 `is_near_duplicate_query()` 檢查是否為幾乎重複的搜尋。如果是，程式不會直接執行，而是回一個 observation，提醒模型不要重複同樣查詢，而要改成更具體的新查詢。這個設計對 Task 1 與 Task 3 特別重要，因為真實搜尋結果常讓模型想重複 broad query。

第二個是 **arithmetic guard**。`is_arithmetic_query()` 會判斷某個 query 是否只是計算式。如果是，程式會回 observation 告訴模型：不要用 Search 做算術，應直接利用已拿到的數字回答。這正是為了符合題目中 Task 1 的 planning / quantitative reasoning 精神。

Section 2: Benchmark Traces 與行為分析（The Evidence）

此部分的 Console trace 我都用最近一次跑出的 RE18.txt

1. Task 1：Planning & Quantitative Reasoning

問題：What fraction of Japan's population is Taiwan's population as of 2025?

Console Trace:

C:\Users\User\Desktop\ReAct Agent>python main.py

==========

Task 1

Question: What fraction of Japan's population is Taiwan's population as of 2025?

==========

--- Step 1 ---

Thought: I should first find Japan's total population as of 2025.

Action: Search["Japan population 2025"]

Observation:

Source: https://www.worldometers.info/world-population/taiwan-population/

--- Step 4 ---

Thought: I now have Japan's total population as of 2025 and Taiwan's total population as of 2025, so I should calculate the fraction directly instead of searching again.

Final Answer: The fraction of Japan's population that is Taiwan's population as of 2025 is approximately 23.6 million / 123.1 million, which is approximately 0.192 or 19.2%.

==========

這一題最重要的檢查點，不是最終數字本身，而是 agent 是否有做出合理的 **Task Decomposition**。題目要求它不要直接猜比例，而是應先找 Japan 的 2025 人口，再找 Taiwan 的 2025 人口，最後再計算比例。

在 `RE18.txt` 中，agent 的行為大致符合這個要求。第一步，它先搜尋 `"Japan population 2025"`，從 observation 中取得與 2025 日本人口相關的資訊，其中一筆結果明確提到 2025 年約為 123.1 million。第二步，它再搜尋 `"Taiwan population 2025"`，取得與台灣 2025 人口相關的結果，並在思考中整理出約為 23.6 million。到了後續步驟，agent 明確表示自己已經擁有兩個 2025 的總人口值，因此應該直接計算比例，而不是再繼續搜尋，最後回答約為 `23.6 million / 123.1 million ≈ 0.192`，也就是約 19.2%。這個流程顯示 agent 有先拆問題，再計算，而不是一開始就猜答案。

不過，Task 1 也是本次 benchmark 中最不穩定的一題。其原因不在於 parser 或 loop 壞掉，而在於真實 observation 經常是多筆搜尋摘要混在一起，其中可能同時含有：

- population page title
- 1950–2025 的年份範圍
- density 而不是 total population
- 鄰近年份而非精準的 2025 值
- 看似相關但未直接顯示所需數字的資料頁

在這種情況下，模型有時雖然其實已經拿到足夠接近的數字，卻會因為 observation 太雜而變得過度保守，甚至想把「最後的除法」再拿去 Search。`RE18.txt` 中就可看到模型一度出現 `"calculate fraction of Japan's population that is Taiwan's population as of 2025"` 這種偏向算術的搜尋行為，但後續仍能在 observation 的提醒與既有資訊下回到正確軌道，直接輸出比例答案。這代表 agent 的規則與保護機制並非完全無效，而是面對真實摘要雜訊時仍有一定不穩定性。

相較之下，`RE14.txt` 顯示了另一種失敗樣態：模型在已查過 `Taiwan population 2025` 後，又試圖重複或近似重複搜尋，因此觸發 duplicate-search guard；之後甚至出現 `Action: None` 這類非法格式，最終在步數上限內沒有成功收斂。這個 trace 很適合放進 report 作為 failure analysis，因為它顯示出問題並不是「不會查資料」，而是 observation 含混雜資料時，模型不一定能穩定決定何時該停止搜尋、何時該直接利用現有數字作答。

總結來說，Task 1 已成功展現出本 agent 具備作業所要求的 planning 結構：先找 Japan，再找 Taiwan，再計算；但也誠實暴露出在 noisy multi-result observation 下，few-shot 與 prompt 對真實 observation 格式的對齊程度，會直接影響穩定性。因此，Task 1 可以作為本 agent 具備 planning 結構的代表性成功案例，但不能解讀為此題已在所有 benchmark reruns 中完全穩定成功。

---

2. Task 2：Technical Specificity

問題：Compare the main display specs of iPhone 15 and Samsung S24.

Console Trace:

==========

Task 2

Question: Compare the main display specs of iPhone 15 and Samsung S24.

==========

--- Step 1 ---

Thought: I should first gather the display attributes for the iPhone 15.

Action: Search["iPhone 15 display size resolution display type refresh rate"]

Observation:

[1] iPhone 15 - Wikipedia

| Display | 15: 6.1 in (150 mm) 2556 1179 resolution, 19.5:9 aspect ratio (~460 ppi density) Super Retina XDR OLED, 60Hz, HDR10, 1000 nits (typ), 2000 nits (peak) supplied by Samsung Display 15 Plus: 6.7 in (170 mm) 2796...

[3] Samsung S24 series tech specs (S24, S24+, S24 FE, S24 Ultra)

Savings: 77.46% Shop Galaxy S24 Display + Size: 6.2-inch + Resolution: 2340 x 1080 pixels, 19.5:9 ratio, 416 ppi + Technology: Dynamic AMOLED + Refresh rate: 120Hz + Peak brightness: 2600 nits Display features + HDR supp...

Source: https://www.backmarket.com/en-us/c/samsung/samsung-s24-tech-specs?srsltid=AfmBOooIqfYlxpus94Is8eEbMdS4gfbmxNz1Fg0tX2ygs2nZJrmUOrCR

--- Step 3 ---

Thought: I now have the display attributes for the Samsung S24, and I should compare the matching display attributes for both phones.

Final Answer: The iPhone 15 has a 6.1-inch or 6.7-inch display with a 2556x1179 or 2796x1284 resolution, a Super Retina XDR OLED display type, and a 60Hz refresh rate, while the Samsung S24 has a 6.2-inch display with a 2340x1080 resolution, a Dynamic AMOLED display type, and a 120Hz refresh rate.

==========

在這一題中，Section 2 所貼的主要 console trace 來自 RE18.txt。從這次完整 run 可看出，agent 的 query strategy 本身是合理的：它先搜尋 iPhone 15 的 display size、resolution、display type 與 refresh rate，再用相同欄位搜尋 Samsung S24 的 matching display attributes，最後直接進行比較。這表示 agent 已理解 Task 2 需要的是具體、對稱且可對照的 technical specs，而不是一般性的手機比較。

不過，RE18.txt 也清楚暴露了這一題的主要困難：iPhone 15 的 observation 來自一個同時包含 iPhone 15 與 iPhone 15 Plus 規格的頁面，因此 snippets 中同時出現 6.1-inch 與 6.7-inch、2556×1179 與 2796×1284 等資訊，導致 final answer 出現型號混雜。這不是因為 agent loop 壞掉，而是搜尋摘要本身就將相近型號放在同一頁，模型若沒有足夠強的 exact model filtering 能力，就容易受影響。

即便如此，這次 trace 仍顯示 agent 有成功抓到作業最在意的 `60Hz vs 120Hz` 差異，因此可作為 Task 2 已具備基本 technical specificity 能力的證據；只是其最終答案品質仍受到 source contamination 影響，尚未在所有情況下都完全穩定。

---

3. Task 3：Resilience & Reflection Test

問題： Who is the CEO of the startup “Morphic” AI search?

Console Trace:

==========

Task 3

Question: Who is the CEO of the startup 'Morphic' AI search?

==========

--- Step 1 ---

Thought: I should search for the CEO directly first.

Action: Search["Morphic AI search CEO"]

Observation:

Source: https://tracxn.com/d/companies/morphic/__VdUjYovcKssIfXUAQ5UHo8pWIndg8FskTen0YI6JFHM

--- Step 2 ---

Thought: I already have a direct statement identifying the CEO from a relevant result.

Final Answer: The CEO of Morphic AI search is Jaynti Kanani.

==========

在 RE18.txt 中，Task 3 的表現相對乾淨。agent 的第一步直接搜尋 `"Morphic AI search CEO"`，保留了使用者問題中的關鍵限定詞，也就是 Morphic、AI、search、CEO。這一點非常重要，因為若 query 被放寬成只有 `"Morphic CEO"`，就容易混入其他不同領域的 Morphic 公司。由於 query 保留了關鍵 disambiguating words，observation 很快出現了與該 startup 較相關的結果，包含指出 Jaynti Kanani 為 Morphic CEO 的內容。agent 在第二步判斷自己已經有直接陳述 requested fact 的 observation，因此不再擴大搜尋，而是直接回答。這正好符合 system prompt 中「若 observation 已直接給出 requested fact，應直接回答，不要再 broaden query」的規則。

這一題之所以表現較好，反而說明了 few-shot 與 prompt 規則的重要性。當 system prompt 明確教模型：

- ambiguous-name query 不可移除關鍵限定詞
- 已拿到直接陳述就要直接回答
- 不要因為其他較不相關結果存在就把 query 放寬

因此，即使這次 trace 中 agent 並未出現明顯的「第一次失敗、第二次修正」長反思過程，它仍展現出一種較弱但合理的 reflection / self-correction 表現：在第一輪搜尋策略上就避免走入錯誤實體，並在 observation 已充分時果斷停止，而不是因為其他混雜結果而盲目再查一次。

---

3. Failure Analysis：失敗樣態與穩定性分析

從多次 benchmark trace 來看，造成不穩定的主因並不是 parser 壞掉，也不是基本 loop 壞掉。實際上，`agent.py` 已經具備固定格式輸出、stop logic、history update、loop limits、duplicate-search guard 與 arithmetic guard 等機制，這些機制本身都可正常運作。真正困難的是：真實 Search API 回傳的 observation 並不像範例那樣乾淨。它常常包含多個摘要、混合不同年份、不同統計口徑、頁面標題、相關但非直接答案的資訊，甚至把相近產品型號放在同一則摘要中。

以 Task 1 為例，agent 有時其實已經看到足以回答的兩個人口值，卻仍然不夠有把握，想再去 search 最後的算術步驟。這說明問題不是它不懂要先查兩個國家人口，而是 observation 的真實格式讓它難以穩定判斷「現在是否已足夠回答」。

以 Task 2 為例，agent 的 comparison 流程本身是正確的，但 search snippets 有時會把 iPhone 15 與 iPhone 15 Plus 規格混在一起。此時 agent 即使 query 寫得合理，仍有可能因為

observation source contamination 而混入不完全相符的資訊。這屬於 retrieval quality 問題，而不純粹是 reasoning loop 問題。

以 Task 3 為例，問題的核心則是 entity ambiguity。只要 query 放得太寬，便會把其他同名 Morphic 公司一起帶進來。因此，這題的穩定度高度依賴 prompt 是否有明確教模型保留關鍵 disambiguating words。當這個策略被 few-shot example 與 system rules 強化後，結果便明顯改善。

綜合而言，本次 benchmark 顯示：
真正影響穩定度的關鍵，並不是 **ReAct loop** 本身，而是 **few-shot prompt** 與真實 **observation** 格式是否足夠對齊。
如果 example 過於理想化，只教模型面對單一、乾淨、明確的 Observation，那麼一旦遇到真實多摘要搜尋結果，它就較容易變得過度保守、誤混資料、或在已足夠回答時仍持續搜尋。

---

4. External Limitation：外部限制與 benchmark 採證方式

在本作業後期進行 benchmark 重測時，外部 Search API 出現了額度耗盡的情況，導致後續 re-run 無法再公平進行。由於本作業明確要求使用真實 Search API，而非自製假搜尋結果，因此一旦外部 quota 用盡，benchmark 的可重現性就會受到影響。這個限制並不代表 agent 架構本身未完成，而是代表後期無法在相同條件下持續重跑測試。

因此，本報告在 Section 2 統一使用 `RE18.txt` 作為一次完整 benchmark run 的主要 console trace，因為該檔案記錄了同一個 `ReActAgent` instance 依序回答三個 benchmark questions 的過程。另一方面，`RE14.txt` 不作為 Section 2 的主要 trace，而是作為補充 evidence，用於 failure analysis 與穩定性比較。

Completion Status / Honest Assessment

本專案已完成作業要求中的核心架構，包括：single general-purpose ReAct agent、few-shot prompting、same agent instance for all three benchmark questions、history update、loop limit、stop logic、以及 real search API integration。
然而，若以 benchmark 穩定度與 reflection 品質的角度來看，部分要求只能算是「已實作並部分展現」，而非在所有 reruns 中都穩定達成。特別是 Task 1 的 quantitative reasoning 與 Task 3 的 self-correction 表現，仍會受真實 observation 格式、搜尋摘要雜訊與 query ambiguity 影響。因此，本報告採取較保守的立場：主張本 agent 已完成核心要求，並以代表性 trace 證明其能力，但不宣稱其 benchmark 表現已完全穩定。

---

5. 結論

本專案完成了一個符合題目要求的 **single general-purpose ReAct agent**。它具備 few-shot prompting、固定 ReAct 輸出格式、stop logic、防 hallucinated observations、history update、

hard loop limit、duplicate-search guard，以及 arithmetic guard。這些機制共同構成了一個能夠對不同問題類型進行搜尋、思考、修正與作答的 agent。

在 benchmark 表現方面，Task 1 顯示 agent 已能做出合理的 task decomposition，而不是直接猜比例；Task 2 顯示 agent 能擷取具體 display specs 並抓到 60Hz 與 120Hz 的差異；Task 3 則顯示 agent 面對歧義名稱時，若能保留關鍵限定詞，便能有效避免錯誤 broaden query。當然，實測也顯示真實 search snippets 的雜訊會影響穩定性，尤其在多筆摘要混合、相近型號混入、或不同年份同時出現時，模型的停止時機與資料篩選能力仍會受到挑戰。

整體而言，我認為本作業已完成 single general-purpose ReAct agent 的核心架構，並初步展現 planning、acting、observation integration 與部分 self-correction 能力。雖然 benchmark 並非每次 rerun 都完全穩定，且其表現仍受真實搜尋摘要品質、題目歧義與外部搜尋限制影響，但已具有代表性的有效 traces，可作為本 agent reasoning 與 action-taking 能力的證據。
